

# Assignment 3

Ankita De, Daqi Xu

March 29, 2016

## Exercise 1

Private Score : 0.89897

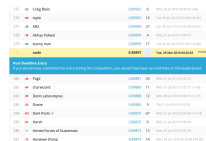

After some tries of default logistic regression model and model tuning (mainly use for-loop to find a better regularization strength), we adopt strategy from Mirosław's code for feature engineering to get a better predict result with the logistic regression model.

Strategy :

1. One hot encoding
2. Feature Engineering

The dataset includes 9 variables, to find the inter-connection between each variables, we group several features together and increase the dimension of variables, then find the good features among those variables until the greedy search can not give back a better prediction. Group of 3 and 4 variables have been tested. Save the selected fea

3. Tuning regularization strength

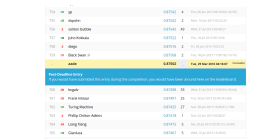

Feature	Importance
age	0.89897
...	...

## Exercise 2

Private Score : 0.87502

We did not use the rollout1 and role code features. We then tuned the parameters in the order : max\_depth and min\_child\_weight, gamma, subsample and colsample\_bytree and reg\_alpha using GridSearchCV from scikit learn.

Feature	Importance
age	0.87502

## Exercise 3

Private Score : 0.91478

Strategy : We used an ensemble of the following :

1. Xgboost with tuned parameters : average of 10 different predictions, each produced using a random seed. Also dropped the roll\_rollup1 and role\_code features.
2. Our logistic regression : using feature selection and one hot encoding
3. The logistic regression of the BSMAN part of the winning solution.

We used weighted average of their predictions in the corresponding weight ratio of 1:27:27.

Solution	Private Score	Public Score	Submitted
